

Disjoint index sets are not enough. A class-stratified split draws S_0 against label counts taken over the whole of S , which contains S_b , so the prior comes to depend on the labels of S_b though the two subsets share no example. A fixed-quota sample is also not the i.i.d. draw the bound assumes, whatever the quotas are computed from. The label-independent partition of the corrected pipeline removes both faults.

solid arrow = permitted dependency
dashed arrow with $\times$ = forbidden dependency
double border = reported quantity
